

Environment, agro-system and quality of food production in Italy

Nicola Dal Ferro, Maurizio Borin

Department of Agronomy, Food, Natural resources, Animals and Environment, University of Padua, Legnaro (PD), Italy

Abstract

In the context of increasing attention towards sustainable and high quality food products, Italy plays a key role in Europe due to its embedded territorial vocation for locally produced food and alternative agriculture systems helping biodiversity and landscape preservation. Here, we report an overview of Italian agriculture by analysing organic farming (OF) and geographical indication (GI) systems and their contribution to the national agriculture. Land use data highlight that OF and GI contribute around 10% to the utilised agriculture area (UAA), with relevant distinctions in terms of regional distribution. While GIs are mostly in the north-central regions (8.5%), OF products are most frequent in the south and on the islands (5.0% of UAA). This trend was observed on the one hand in Trentino-South Tirol, Veneto and Friuli-Venezia Giulia (%UAA GI/%UAA OF>5.9), and on the other in Calabria, Basilicata and Sicily (%UAA GI/%UAA OF<0.1). Similarly, both systems are widespread in less-favoured areas in terms of agricultural intensification, providing support to preserve agro-systems and reduce land abandonment.

Introduction

High quality and authentic agri-food products, mostly recog-

nised as coming from organic farming or labelled with geographical indications (Aprile *et al.*, 2012), are increasing in Europe as consumers consider quality, and its association with agro-ecological characteristics (Deselnicu *et al.*, 2013), the most important purchasing factor (*e.g.*, Malorgio *et al.*, 2008; Hinojosa-Rodríguez *et al.*, 2014; Special Eurobarometer 410, 2014). In this context, the Universal Exposition that was held in Milan during 2015, entitled *Feeding the Planet, Energy for Life*, emphasised the need for sustainable agricultural products and the importance of quality food.

The adoption of quality brands in Europe in the 1990s was intended to encourage the diversification of agricultural production and protect product names and processes that are linked to a geographical area through the promotion of Protected Designation of Origin (PDO) and Protected Geographical Indication (PGI) labels (*i.e.*, geographical indications, GI), under Council Regulation (EEC) No 2081/92 (European Commission, 1992). Moreover, by adopting Regulation (EEC) No 2092/91 (European Commission, 1991), the European Council of Agricultural Ministers introduced organic farming (OF) and the labelling of organic farm produce and foods with the aim of promoting sustainable alternatives to conventional agriculture. In spite of being adopted with different purposes, over the years both schemes confirmed their vocation as producers of quality food. Their assembly into a single, although varied, product category (called *sustainable produced food*) was also proposed by Vermeir and Verbeke (2006) since they both reflect two different components of sustainability: i) a social component in support of the local agri-food sector and rural citizens – in the case of geographical indication products; ii) an environmental component related to sustainable use and management of natural resources – in the case of organic farming products.

Since 2004, organic farmland in the EU increased by approximately 76% (+3% in 2013 on a yearly basis), involving an increase of the organic market that reached +55% (+6% in 2013 on a yearly basis) (Willer and Schaack, 2015). Similarly, the sales value of geographical indication products registered in the EU 27 increased by 12% between 2005 and 2010 (Chever *et al.*, 2012), while their area of production is strictly related to their specific geographical origin and regulations.

In addition to economic return, quality produced foods have been recognised as contributors to maintaining biodiversity and enhancing environmental benefits. In particular, organic farming was proposed in the EU as a certification process to minimise human impact on the environment, by ensuring that agriculture operates in the most natural way. Among others Tuomisto *et al.* (2012), in a meta-analysis study conducted on European data, showed that organic farming systems had generally lower environmental impacts than conventional farming, although they also stated that there was not an optimal system for all the measures that were adopted to improve environmental practices as also found by others (Dal Ferro *et al.*, 2016). Although environmental protection is not explicitly addressed either in EU legislation or in national requirements for the protection of geographical indica-

tions, several studies reported their general favourable effect. An overall capacity was observed to maintain multifunctional agricultural systems (Belletti *et al.*, 2003), landscapes and biodiversity thanks to the protection of small-scale production and conservation of local ecosystems (Bérard and Marchenay, 2006). However, some weaknesses were also highlighted, such as the risk of favouring genetic erosion in plant varieties and animal breeds (Thévenod-Mottet, 2010). In this context, some studies reported that EU member states with a strong tradition and well-developed systems of geographical indication protection (in particular France and Italy) are also characterised by the highest level of environmental care (Belletti *et al.*, 2015).

Italian agriculture is recognised worldwide as providing agri-food products and brands of prime quality. Within EU member states, Italy is one of the most important in terms of utilised agricultural area (UAA) and sustainably produced foods. An integrated analysis of the Italian agro-systems involved in quality food production is therefore a key aspect for assessing the agricultural sector's state of the art and evaluating potential future developments. Since both systems can indicate increased environmental quality and provide multiple ecosystem services, although partly addressed towards different environmental protection issues (*e.g.*, low human impact in OF; landscape protection in GI), the understanding of their characteristics and relationship in the national context is crucial to address targeted agri-environmental policies. In this context, this study provides an overview of OF and GI systems and their relationship across Italy and their influence on the agricultural sector. In particular, the paper aims to describe: i) size and distribution of OF and GI farms in comparison to the total farms in Italy; ii) the distribution of OF and GI systems in the different regions, in relation to the respective farming systems; iii) the UAA cultivated with OF and GI in the different elevation zones and macroareas in Italy; iv) the repartition of the main crop categories within both OF and GI systems; v) the distribution of GI agri-food products and wines in the Italian macro regions and the national contribution with respect to EU and World products.

Materials and methods

A general overview of different agricultural land uses at a national level is provided by the National Institute of Statistics (ISTAT), which is the main supplier of official statistics in Italy. In this paper, data from the last national agricultural census (hereafter labelled as ISTAT 10), conducted in 2010 (ISTAT, 2010) at the municipal level, were used to study the Italian agricultural sector at the national (NUTS-1), regional (NUTS-2) and sub-regional level. In particular, a comparison was done between conventional farming systems and those labelled according to OF and GI in terms of localisation, average farm size (ha), area investment (ha) per product category (*e.g.* cereals, vegetables, *etc.*). Moreover, municipal data were grouped into sub-regional *macroareas* following the ISTAT classification as follows (Figure 1A): North, comprising Aosta Valley, Piedmont, Liguria, Lombardy, Trentino-South Tirol, Veneto, Friuli-Venezia Giulia and Emilia-Romagna regions; Centre, comprising Tuscany, Marche, Umbria and Lazio regions; South, comprising Abruzzo, Molise, Campania, Apulia, Basilicata and Calabria regions; Islands, comprising Sardinia and Sicily. Following the ISTAT classification, a comparison also was done on data belonging to different altitudinal areas (mountain, hills and plain) (Figure 1B).

Additional information was obtained from the CORINE (Co-

ordination on INformation of the Environment) Land Cover geographic database at national (NUTS-1) and regional (NUTS-2) level. CORINE has a minimum cartographic unit of 25 ha and a geometric accuracy of 100 m. It maps homogeneous landscape patterns, *i.e.* more than 75% of the pattern has the characteristics of a given class from the nomenclature. Information from the CORINE Land Cover database used here refers to agricultural areas (Level 2) as divided in Arable lands, Permanent crops, Pastures and Heterogeneous agricultural areas. The time reference for CORINE Land Cover classification is 2012 (hereafter labelled as CLC 12; CLC, 2012).

Organic farming in the EU has been regulated since the beginning of the 1990s. The uniform EU regulation for the production, control, labelling and import of organic products has been revised several times since its introduction [Regulation (EEC) No 2092/91; European Commission, 1991] and has been replaced with the current Organic Regulation (EC) 834/2007 (European Commission, 2007) and further minor changes. A special mention must be made about organic wine production. Until 2012 an *organic wine* was intended as produced from organic grapes only. In 2012, the EU approved a regulation governing the production of organic wine and the option to put the EU organic logo on the label, as with other organic foods. The novelty is that organic wine must be produced from organic grapes and vinified according to EU specific regulations as per other agri-food products [Regulation (EU) No 203/2012; European Commission, 2012a].

Two EU schemes, known as Protected Designation of Origin (PDO) and Protected Geographical Indication (PGI), are here integrated in the more general Geographical Indication (GI) wording, including place-based agri-food and wine products. In 1992, a regulation (EC 2081/92; European Commission, 1992) was issued with the aim of protecting PDO and PGI and giving a certain guarantee to consumers by defining the conditions, procedures, and extent of protection. The legislative framework adopted by the EU and that is currently in force [Regulation (EU) No 1151/2012; European Commission, 2012b] provides that producers apply for the GI protection. They are required to submit an application accompanied by product specifications that contain rules for the production process and the area within which the product is produced, thus linking the agri-food production with specific rural culture and local geographical aspects in the definition of *terroir* (Bérard and Marchenay, 2006). Once again, the wine sector followed a different piece of legislation and its integration within the same legislative scheme as per other agri-food products occurred with Regulation (CE) No 479/2008 (European Commission, 2008).

International statistics on the number of GI products in the different countries were obtained from the official EU web pages regarding agri-food (<http://ec.europa.eu/agriculture/quality/door/list.html>; last update 26/01/2017) and wine (<http://ec.europa.eu/agriculture/markets/wine/e-bacchus>; last update 26/01/2017), while the number of regional GIs across Italy (agri-food and wine products) was obtained from the Italian Ministry of Agriculture web page (<https://www.politicheagricole.it>; last update 26/01/2017).

Results and discussion

The Italian environment

According to Finke *et al.* (1998) Italy is characterised by a wide variation of climatic conditions, from temperate to

Mediterranean, suggesting the interaction of a continental climate (northern and central-northern areas) with that of the Mediterranean basin (centre, south and islands). Moreover, the diversification of almost all the national regions in several elevation zones (plain, hill and mountain), from the sea level (surrounding almost all the country) to the high mountains in the north (the highest peak in Europe is Monte Bianco in the Aosta Valley region,

4810 m asl) is a second major aspect characterising the national territory. Descriptive statistics for simplified climatic regions are reported in Table 1 (L'Abate and Costantini, 2004). By overlaying climatic-oro-graphic aspects with the pedological characteristics of Italy (Costantini *et al.*, 2004; Costantini *et al.*, 2013), a national fragmentation can be noticed that gives 43 unique pedo-climatic areas (Figure 1D). In this context, the northern regions have the

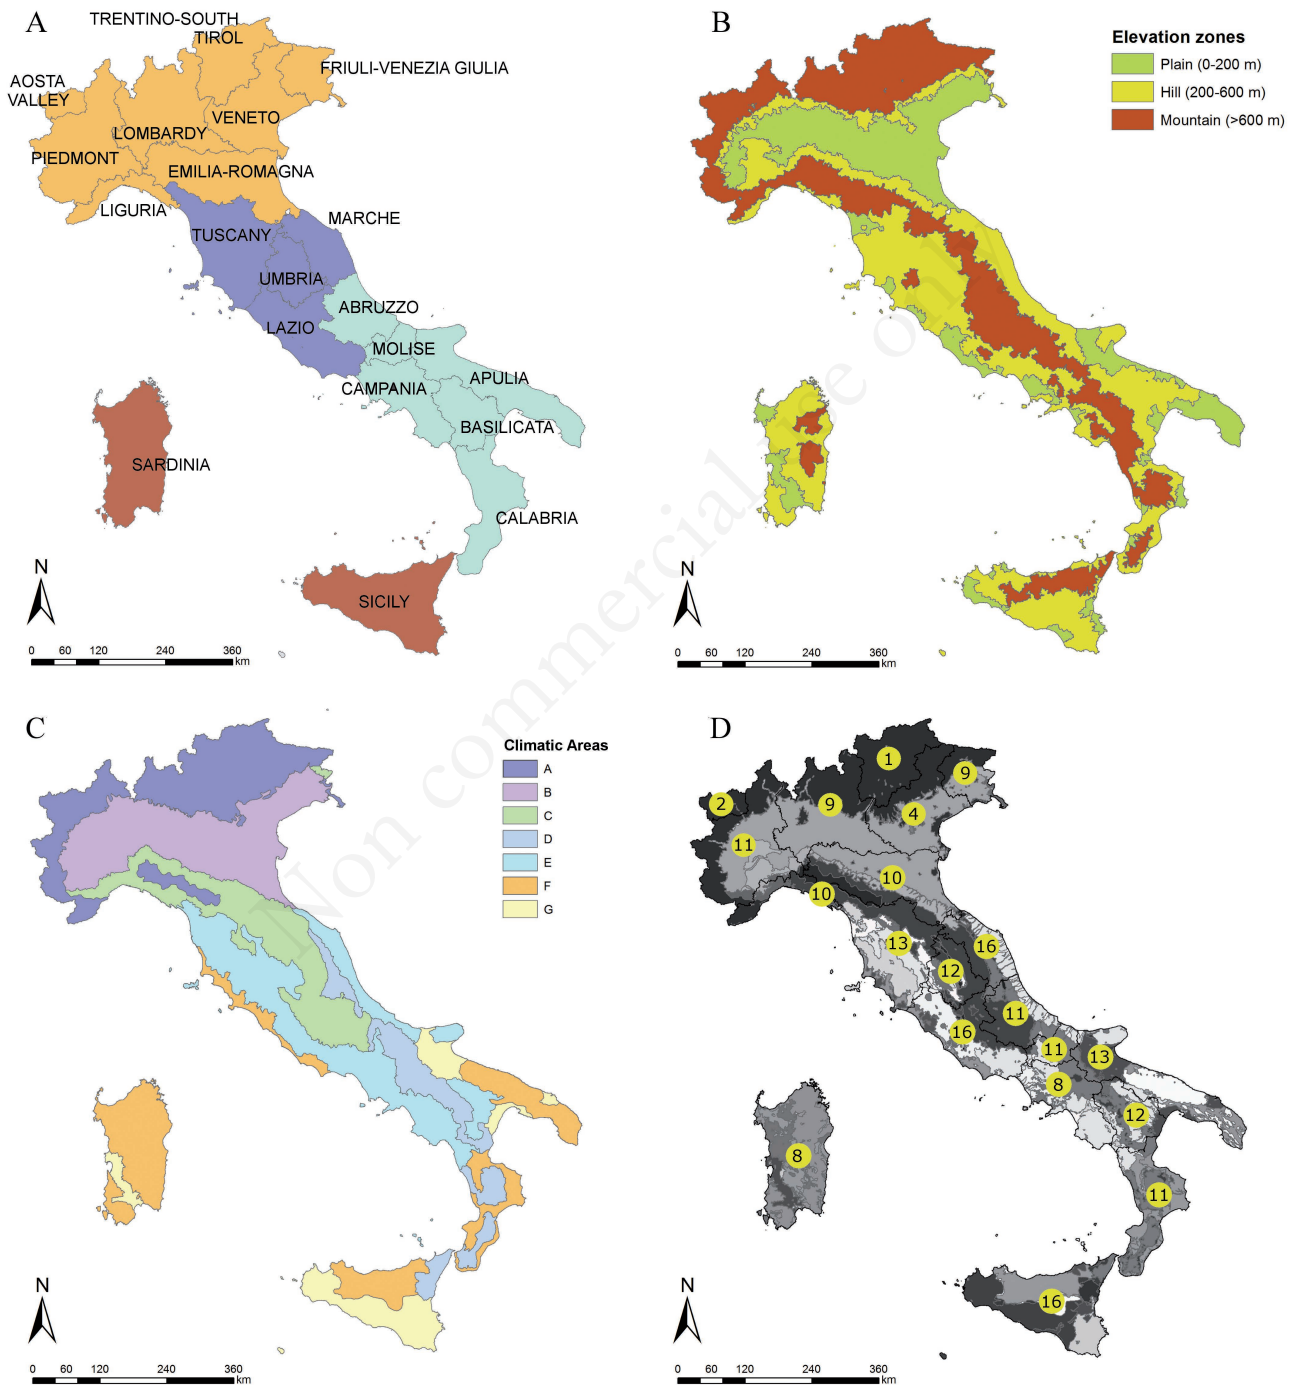

Figure 1. Regions of Italy (A) as labelled with different colours to define North, Centre, South and Islands macroareas; elevation zones (B) and climatic areas (C); number of pedo-climatic units per region as a result of climatic and pedological overlay (D).

lowest territorial diversification (7.0 pedo-climatic units, on average), while central Italy has the highest (14.3, on average). The south and islands account for 11.0 and 12.0 pedo-climatic units on average. This diversity is not related to the territorial extensions of the regions since Tuscany, Umbria, Lazio and Marche (central regions) occupy only 19.7% of the national territory, whereas the north occupies the largest area (38.7%).

Italian agricultural systems

Italy’s utilised agricultural area (UAA) currently occupies 42.6% of the territory, ranging from a minimum of 37.0% in the centre (Lazio, Marche, Tuscany and Umbria regions) to a maximum of 50.9% on the islands (Sardinia and Sicily regions). A comparison with historical data underlines a negative trend of UAA in Italy, which decreased from 17.5 million ha (ca. 58% of national area) in 1970 to the current 12.9 million ha, with an average annual decrease of -0.65% (Figure 2). By contrast, since 1975 the UAA in the EU-9 has remained almost stable at over 80 million ha according to the farm structure survey database (EUROSTAT, 2010). However, there has been an increase of UAA on the Italian islands since 2000 and a slowdown of the negative trend, particularly in central Italy.

A general overview of Italian agriculture land use is provided by land cover maps from the Corine Land Cover 2012 inventory (Table 2). More than half of the agricultural land is occupied by arable lands (53.5%), which include both rainfed and irrigated fields, while permanent crops (e.g., vineyards, olive groves, etc.) cover 14%, with a strong differentiation between the north-centre

(8.5%, on average) and south-islands (18.6%, on average) macroareas. Pastures and meadows are instead quite common in the northern regions reaching average values of 12.1%, thus 9.4% more than the average national value (Table 2). This high figure in the north is mainly due to Aosta Valley and Trentino-South Tirol regions where pastures and meadows cover ca. 40% of UAA (Figure 3).

Land use data aggregation generally highlights a good correspondence with the CLC 12 ones (Figure 3): in particular, a good correlation was observed for arable lands ($y=1.02x + 2.3$; $R^2=0.90$), estimated as 54.5% of the national territory (+1.0% with respect to CLC 12), and permanent crops ($y=x + 5.1$; $R^2=0.77$), estimated as 18.5% of the national territory (+4.5% with respect to CLC 12). A mismatch was observed comparing the remaining UAA since land use data report that 26.7% is managed as pastures and meadows and only 0.25% for other agricultural uses (Table 2). This discrepancy was already observed by Pelorosso *et al.* (2009), who stated that marginal areas with low human impact (e.g., meadowlands) are likely overestimated by census data because they may no longer be farmed and thus subjected to spontaneous recolonisation. As a result land use data may suffer from a low level of reliability, particularly for those areas that are subjected to abandonment. In contrast, cartographic data (here, CLC 12) are more easily validated in the field, although the minimum mapping unit of CLC 12 (25 ha) may result in an overall increase of poorly defined categories (i.e., heterogeneous areas/other uses), which often correspond to a mixture of non-uniform areas (agricultural lands combined with natural vegetation, complex cultivation pat-

Table 1. Descriptive statistics of climatic regions of Italy.

ID	Climatic areas	Annual temperature (°C)	Annual rainfall (mm)	Elevation range (m)	Wettest months	Driest months	Extension (%)

Figure 3. Relationship between regional land cover (CLC 12) and land use (ISTAT 10) data.

terns, etc.). Conversely, field surveys likely classify them according to more defined categories (e.g. pasture, arable lands, etc.). This is particularly emphasised in the case of Italy, where estimates of land fragmentation (the average farm size is only 7.9 ha, generally implying small field size) are similar to those reported in similar studies conducted in Greece (Benaki *et al.*, 2012). In fact, the authors observed a discrepancy between Corine Land Cover data and those reported in the Farm Structure Survey for Greece that was partly explained by the small farm size. Lastly, heterogeneous/other areas as defined by the Italian national census represent only 0.25% of UAA, although their contribution to increasing landscape diversity is relevant since they are mainly woodlands, buffer zones and unproductive/naturalised areas.

The high quality agricultural sector in Italy

Italy, with 1.3 million ha, is the second European country for total organic agriculture area, following Spain (1.6 million ha) and followed by France and Germany (1.1 million ha each). Worldwide, only Australia (17.2 million ha), Argentina (3.2 million ha), USA (2.2 million ha) and China (2.1 million ha) have larger areas of OF systems than Italy (Willer and Lernoud, 2015). OF contributes 781,489 ha to the national UAA, corresponding to 6.1% of total UAA and ranging between a minimum of 3.7% in the plain areas to a maximum of 8.3% in the hilly ones (Table 3).

In absolute terms, the north-centre regions have less OF systems than the southern ones and the islands as they occupy only 29% (227,139 ha) of the total organic farming UAA, while their contribution to the national agricultural land is 52.5%. This is also confirmed by percentage data (Figure 4A), which show a general increase towards larger OF areas from north, to south and the islands. In particular, the southern regions of Calabria and Basilicata have the most land managed following OF systems (up to 18%), while Aosta Valley (north-west), Trentino-South Tirol, Friuli-Venezia Giulia and Veneto (north-east) reach a maximum of only 1.5%. This geographical trend is instead not observed for the average OF holding size at regional level (Figure 4B), which ranges between a minimum of 5.4 ha (Trentino-South Tirol) and a maximum of 43.8 ha (Sardinia) resulting, on a national scale, as double (15.9 ha) that of the average farm size (Table 3). Nevertheless, it was observed that organic farms are also distributed (*i.e.*, as generally the farms in Italy) in terms of altitudinal areas, with the largest ones being more frequently found in the mountains than in the hilly and plain areas (Table 3).

Within the same macroarea (Figure 5), it can be noted that OF is generally more developed in the mountain and hilly areas, covering 5.3 and 8.3% of total UAA, than in the plain areas where, on the contrary, only 3.7% of farmland is managed following OF certifications. A general overview of land use repartition within OF

systems is proposed in Table 4. In this context, large areas that adopt organic pasture both in the north and on the islands, as well as those managed with organic cereals (mainly wheat) and olive groves in the central and southern regions (Table 4), are explained by the different incidence of altitudinal areas. In fact, agricultural intensification is more difficult in hilly and mountain areas than in the lowlands due to biophysical and management limitations

(Parrott *et al.*, 2002), thus encouraging the adoption of alternative systems (*e.g.*, organic farming) that can improve agro-system multi-functionality with quality products, landscape and environmental preservation (*e.g.*, Ronchi and Nardone, 2003). This is particularly true for the northern regions, where a positive correlation ($R^2=0.7$, $P<0.001$) was found between the land percentage of total OF and hilly areas, emphasising a distinction between intensive

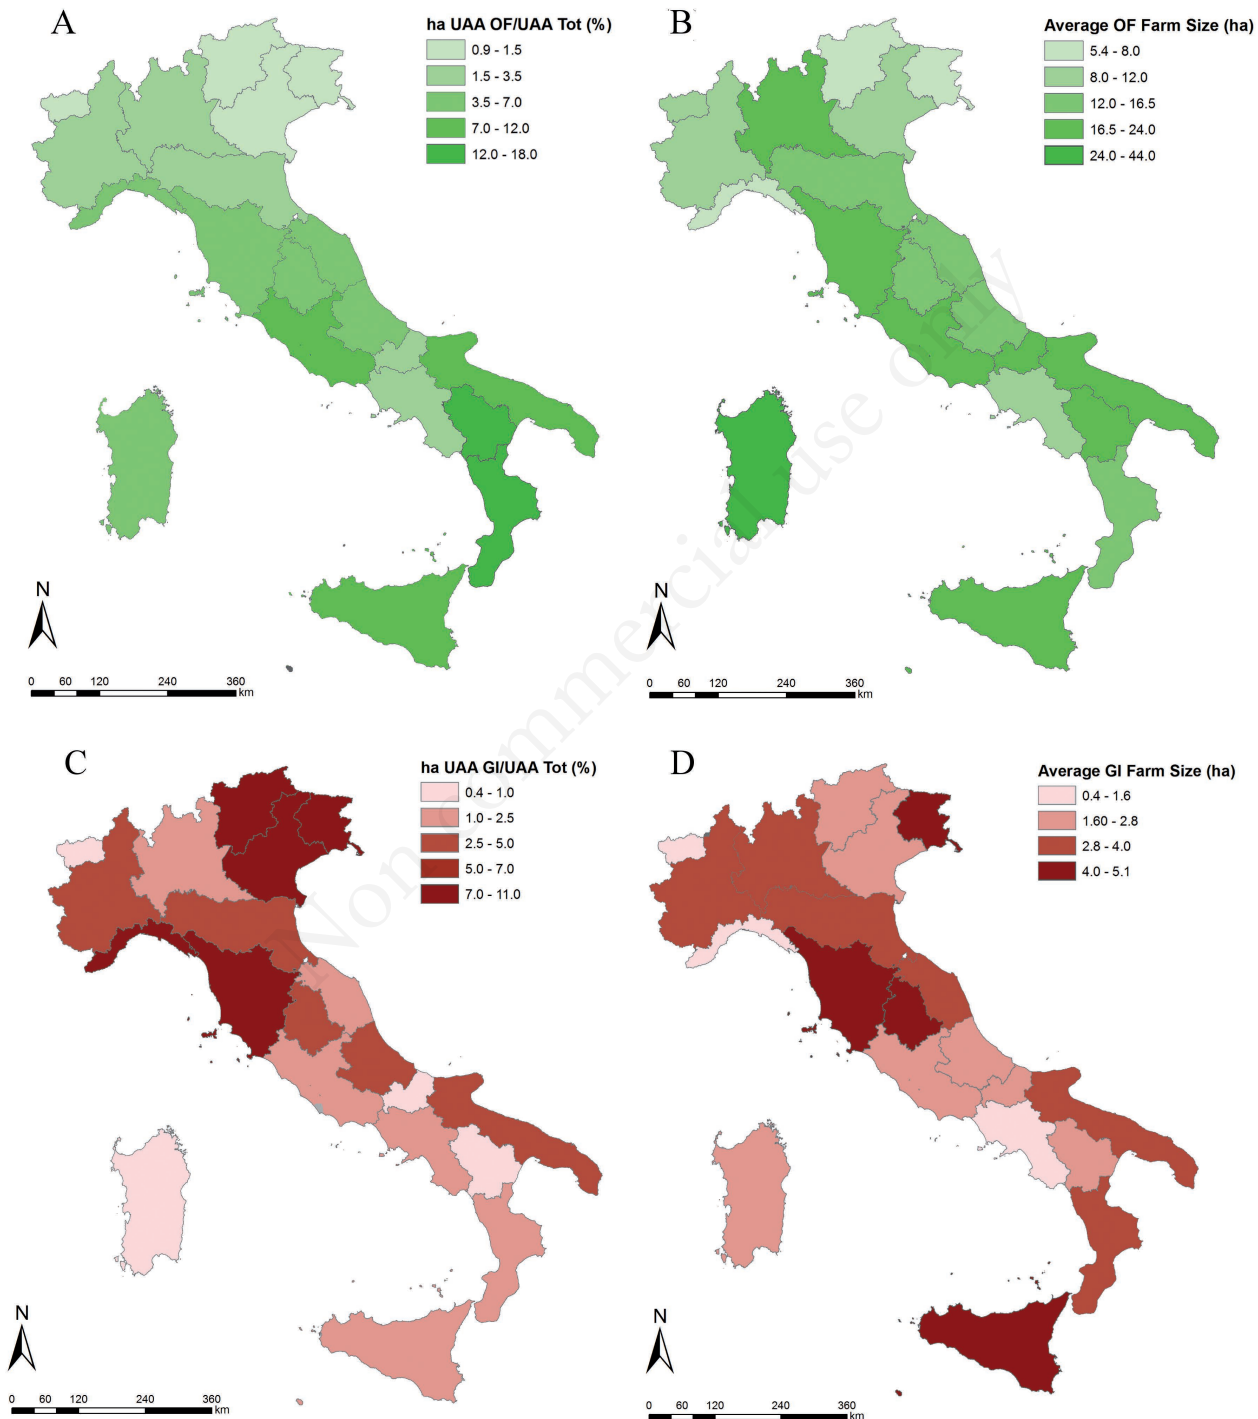

Figure 4. Utilised agricultural area and average farm size for organic farming (A and B) and geographical (C and D) indications in the Italian regions (data source: ISTAT, 2010).

agriculture (in the lowlands) and a wider diversification in less favoured areas. Vineyards play only a secondary role in the overall organic land use. In this case, two different factors likely contribute to limiting the diffusion of organic wine production: primarily, it must be noted that a specific regulation (EU No 203/2012) for organic wine production was introduced only in 2012, thus not yet been approved at the time of the national agricultural census and therefore limiting the potential wine market; secondly, some authors argue that the issue of organic vs conventional systems would be of limited importance for wine since the country of origin is consistently of greater importance than the production method when it comes to wine purchasing decisions (e.g., Mann *et al.*, 2012), although recent statistics reported that in some European countries (*i.e.*, France, Croatia) wine represents an important part (*ca.* 10%) of the organic market (Willer and Lernoud, 2015). Finally, fruit and vegetables are of considerable importance so that, in the north, represent 11.9 and 6.6% of total UAA (Table 4), thus tripling their contribution with respect to the overall agricultural system.

There are 3374 geographical indication products worldwide (labelled following the EU certification of PDO or PGI products), divided between the agri-food (1432) and wine (1942) sectors (Table 5) (last update, 26/01/2017). Most products are from EU-28 members (total 3311) and Italy, which is the leading country within the EU-28 with 833 GI products (295 agri-food and 538 wines sectors), contributes 25.2% of the total (Table 5). France and Spain are the second and third countries in terms of total GI products with 451 and 144, respectively.

The number of GI products per region (Figure 6A), which was provided by the Italian Ministry of Agriculture, shows that Emilia Romagna has the largest number of typical agri-food products (43), followed by Veneto (35), Lombardy (34) and Sicily (30), while Molise and Aosta Valley only have 5 and 4, respectively (Figure 6A). Piedmont and Tuscany are instead the richest regions in terms of GI wines (both 58), followed by Veneto (52) (Figure 6B). As a result, the northern and central Italian regions are those with the largest number of GI products. Nevertheless, the analysis of regional GI products density (*i.e.*, number GI/10,000 ha of total

UAA; Figure 6D) reveals different results: Liguria is the leading region, with 3.6 GI/10,000 ha, followed by the north-eastern regions (Veneto and Friuli-Venezia Giulia) and Tuscany with 1.1 GI/10,000 ha, while the lowest GI density (on average, 0.35GI/10,000 ha) is found on the islands and in southern regions, particularly Apulia and Basilicata. These results suggest that the adoption of GI is much more relevant where there is a higher level of land diversification and heterogeneous areas (unproductive/naturalised areas, buffer zones, marginal woodlands, *etc.*). Indeed, a

UAA, utilised agricultural area.

positive correlation ($R^2=0.75$; $P<0.01$) was observed between heterogeneous areas (as defined by land use data) and regional GI products density, emphasising their benefits in the preservation of more extensive agricultural practices (Lamarque and Lambin, 2015) and cultural landscapes (Riccheri *et al.*, 2007). Nevertheless,

no general correlation between the Italian pedo-climatic diversity and OF-GI systems was observed, likely due to a much more complex interaction with local aspects (*e.g.*, rural culture and local economies). Finally, some uncertainties could arise from the GI density index since GI and UAA referred to different years,

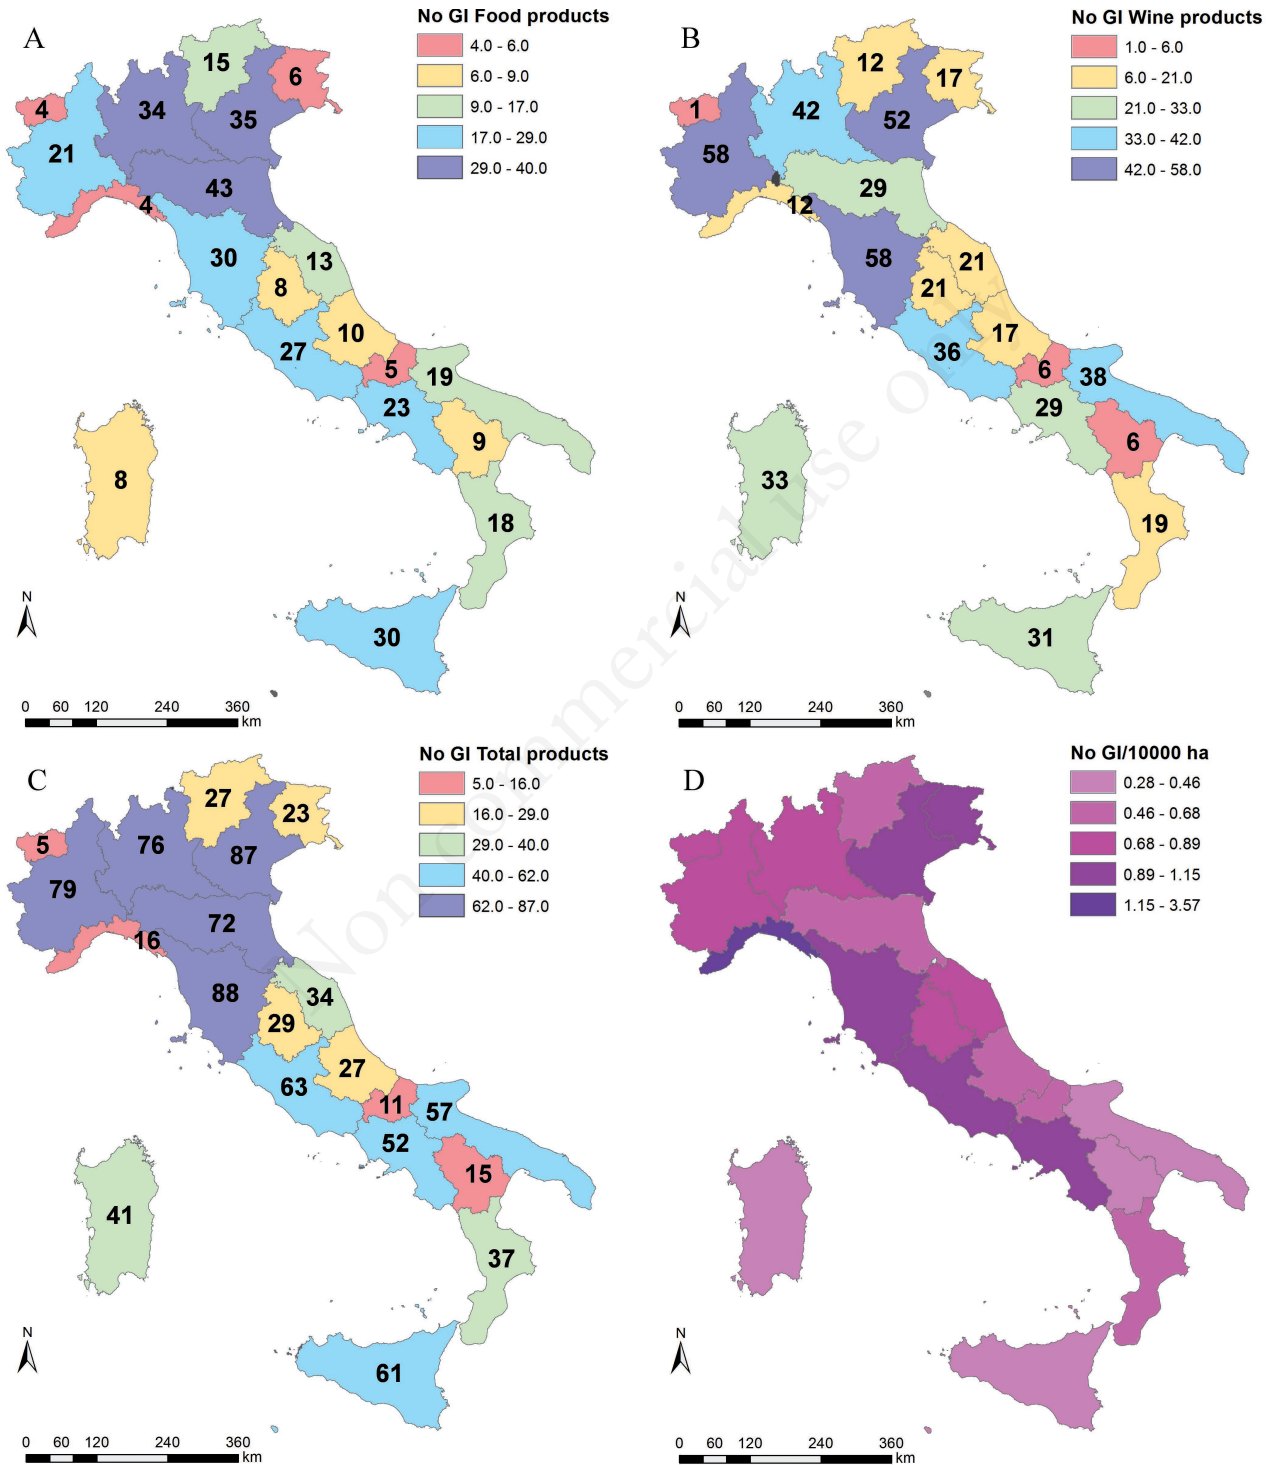

Figure 6. Regional distribution of geographical indications in Italy (data source: Italian Ministry for Agriculture database).

although differences in the comparison between regions are negligible since slightly affected by changes in the UAA.

Contrary to what is observed for OF, geographical indications are mostly widespread in northern and central Italy (Figure 4C), covering up to 11% of total UAA in Trentino-South Tirol, followed by Tuscany (9.8%), Veneto (7.5%) and Friuli-Venezia Giulia (7.1%). Conversely, only 0.4% of total regional UAA is managed for GI production in Basilicata. As a result, the northern regions of Trentino-South Tirol, Veneto and Friuli-Venezia Giulia are those markedly inclined towards GI products, while the southern regions of Calabria, Basilicata, Apulia and Sicily mostly favour OF ones (Figure 7). According to Vermeir and Verbeke (2006), this reflects that different schemes are selected to provide quality food products across Italy whose adoption (either OF or GI systems) contributes to the improvement of agro-system sustainability. Land used for GI products is 3.6% in Italy, while land for OF is 6.1%. As a result, at national level, UAA managed for labelled quality products (GI and OF) contribute nearly 10% of the total. Nevertheless, since OF and GI are seldom characterised by distinct ways to target different environmental issues (e.g., Bérard and Marchenay, 2006; Fleskens *et al.*, 2009; Stockdale *et*

al., 2001), such as maintaining landscape and biodiversity, lowering human impacts on soil and water resources, etc., their combination into an more integrated system is also advisable.

A significant decrease in regional farm size was observed for GI (Figure 4D) with respect to OF (Figure 4B), since a maximum of 5.1 ha/farm for GI (found in Friuli-Venezia Giulia) is even lower than the minimum one in OF (Trentino-South Tirol). Hilly areas are more frequently managed for GI productions than the mountains and lowlands, reaching a peak of 11.7% in the north (Figure 5B), apart from on the islands where the UAA of geographical indications are greater in the plain areas. In general, these observations are in agreement with others: for instance Barjolle and Sylvander (2002) reported that several GI products are located in less-favoured lands in terms of agricultural intensification (e.g., hilly or mountain areas) as they allow for more small-scale labour-intensive economic efficiency. These aspects might be integrated with those discussed by Bérard and Marchenay (2006), who argued that GI farming is an alternative model to the essentially productive one, associating localised extensive practices with biological and landscape diversity. GI areas are mostly managed with permanent crops (Table 4) from north to south, especially vineyards (96.4% of total UAA at national level) and olive groves (16.8% of total UAA at national level), which are partly replaced by citrus groves on the islands (9.7%). As a result, the great contribution of wine products to the total number of GI ones (Table 5, 66%) is also supported by the total area of vineyards. In this context Cohen *et al.* (2015), analysing the plant biodiversity of Mediterranean agricultural systems as indicator of multifunctional and sustainable cultural landscapes, observed medium to high plant diversity in vineyards and olive groves where economic valuation relies not only on productivity, but also on heritage and landscape values, promoting high quality products. These findings corroborate previous results where the authors considered arboriculture *per se* as an intermediary case positioned between intensive and extensive agro-systems due to average or little disturbance if compared with other types of farming (Bruggisser *et al.*, 2010; Camarsa *et al.*, 2010).

Table 5. Distribution of geographical indications regarding agri-food and wine products (data from European and the Italian Ministry of Agriculture databases).

	Agri-food	GIs (n) Wines	Total	Italy's contribution (%)
North	162	223	385	-
Centre	78	136	214	-
South	84	115	199	-
Islands	38	64	102	-

GIs, geographical indications.

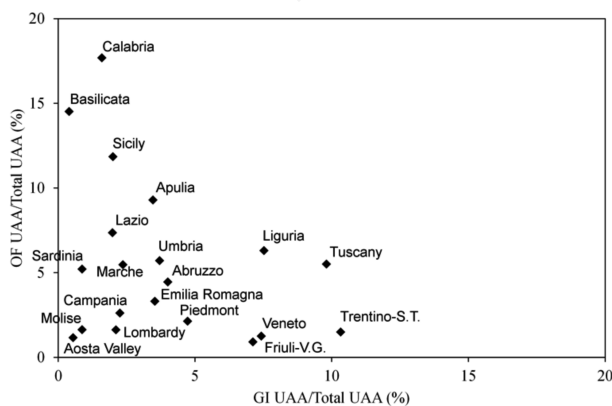

Figure 7. Relationship between regional distributions of utilised agricultural areas for geographical indications and organic farming (data source: ISTAT, 2010).

Conclusions

Italian agriculture for quality food production is widely spread across the national territory, highlighting a major role in the European context that is favoured by a great variety in terms of pedo-climatic and orographic conditions. OF and GI systems cover around 10% of the national UAA, generating almost 25% of the Italian agriculture value production. Organic farms are generally larger than the average national size, while GI farms are the opposite. Different dynamics in terms of farm size and agricultural systems diffusion were observed in the different regions, particularly due to their pedo-climatic and orographic characteristics. In this context, OF are generally more frequent in southern Italy and on the islands, particularly in the hilly and mountain areas. By contrast, GI farms, mostly found in the central and in the northern regions, are located in less-favoured lands in terms of agricultural intensification (e.g., hilly or mountainous areas) as they allow for more small-scale labour-intensive economic efficiency. In this context, they play a positive role in preserving the presence of agriculture in these geographical conditions and, more generally, in preventing the abandonment of land.
